

# Anonymity and Rapid Mixing in Cryptographic Protocols

Mirosław Kutylowski

this talk concerns joint work with Artur Czumaj, Marcin Gomułkiewicz and  
Marek Klonowski

## Significant achievements of cryptography

- ▶ data encryption
- ▶ digital signatures
- ▶ establishing keys between remote parties
- ▶ authentication protocols
- ▶ ...
- ▶ but problems with anonymity of communication

## Communication systems

- ▶ messages can be kept secret
- ▶ authentication through MAC - nothing can be changed without being noticed
- ▶ how to hide that two parties are communicating??

## Need of anonymity in communication

- ▶ business to business communication
- ▶ consumer protection
- ▶ privacy protection
- ▶ economic and political security of a country

## Assumptions about an adversary

Many models possible, each of them might be relevant

- ▶ passive
  - ▶ adversary can eavesdrop the whole traffic
  - ▶ adversary can eavesdrop a constant fraction of traffic
- ▶ active – adversary can insert and delete messages
  - ▶ everywhere
  - ▶ at a constant fraction of nodes

## Anonymity techniques – all-to-all

- ▶ everybody sends an encoded message to all possible recipients at every moment

## Anonymity techniques – all-to-all

- ▶ everybody sends an encoded message to all possible recipients at every moment
- ▶ works only for a small number of participants
- ▶ can be implemented in a token ring

## Mixes

- ▶ a number of messages enter a mix simultaneously
- ▶ they are recoded by a mix
- ▶ and permuted at random before outputting
- ▶ no connection between input and output can be derived  
appropriate encoding

## Networks of Mixes

- ▶ cascades of mixes – mixes run by different parties
- ▶ parallel processing – using small mixes to permute large number of packets

## Networks of Mixes

- ▶ cascades of mixes – mixes run by different parties
- ▶ parallel processing – using small mixes to permute large number of packets

Major problem:

- ▶ how many mixes are to be used

## DC nets

- ▶ Gumiś or Mixer wish to send a bit to me without revealing who sends
- ▶ they toss a coin, the result is  $b$
- ▶ if  $X$  does not send a bit, he sends  $b$ ,
- ▶ the sender sends  $b$  for transmitting 0, and  $1 - b$  for transmitting 1
- ▶ decoding: XOR of bits received

## DC nets

- ▶ Gumiś or Mixer wish to send a bit to me without revealing who sends
- ▶ they toss a coin, the result is  $b$
- ▶ if  $X$  does not send a bit, he sends  $b$ ,
- ▶ the sender sends  $b$  for transmitting 0, and  $1 - b$  for transmitting 1
- ▶ decoding: XOR of bits received
  
- ▶ perfect anonymity
- ▶ problems with scalability

## Bulletin Board

- ▶ a shared broadcast channel
- ▶ encrypted messages
- ▶ everybody can receive, but who can decode??

# Onions

- ▶ messages are sent along (random) paths chosen by the sender
- ▶ each server on the path knows only the predecessor and the successor on the path
- ▶ retrieving any other information (final destination, source,...) from the onion is infeasible

# Anonymity

What does *anonymity* mean?

- ▶ one cannot deduce a destination of a message sent by a single user

# Anonymity

What does *anonymity* mean?

- ▶ one cannot deduce a destination of a message sent by a single user  
OR

# Anonymity

What does *anonymity* mean?

- ▶ one cannot deduce a destination of a message sent by a single user  
OR
- ▶ any significant data on the protocol participants cannot be deduced

## Why anonymity definition is important

Important case - electronic election schemes

- ▶ Eve analyses the votes, and derives probabilities that Alice voted for  $X$ , for each single  $X$
- ▶ if probability distribution is close to uniform, then the scheme is often told to preserve anonymity.

## Why anonymity definition is important

Important case - electronic election schemes

- ▶ Eve analyses the votes, and derives probabilities that Alice voted for  $X$ , for each single  $X$
- ▶ if probability distribution is close to uniform, then the scheme is often told to preserve anonymity.

**FALSE!**

## Why anonymity definition is important

- ▶ Eve may be unable to derive preferences of Alice

## Why anonymity definition is important

- ▶ Eve may be unable to derive preferences of Alice
- ▶ but can deduce that Eve and Jurek voted for the same party with probability 99%

## Why anonymity definition is important

- ▶ Eve may be unable to derive preferences of Alice
- ▶ but can deduce that Eve and Jurek voted for the same party with probability 99%
- ▶ it remains to buy the information from Jurek

## Prior work

Ron Berman, Amos Fiat, Amnon Ta-Shma say:

- ▶ *Literally dozens (hundreds?) of papers since, dedicated conferences, etc., etc.*
- ▶ *Many implementations*
- ▶ *Typical paper:*  
*Attack on prior protocol(s)*  
*Suggest new protocol*  
*Repeat*
- ▶ *Very few attempts to give rigorous definitions, let alone proofs*
- ▶ *Notable exception: Rackoff and Simon, 1993*

## $k$ -anonymity

- ▶ used in databases with sensitive information
- ▶ each user has to be undistinguishable from some  $k$  other users

## $k$ -anonymity

- ▶ used in databases with sensitive information
- ▶ each user has to be undistinguishable from some  $k$  other users

Problem:

- ▶ low level of anonymity
- ▶ suitable if one can control knowledge of an adversary and block further queries

## Anonymity set

- ▶ let  $A$  be the set of all user that are the recipients of a message with a positive probability
- ▶  $A$  called the anonymity set of this message
- ▶ anonymity measure: the size of  $A$

## Anonymity set

- ▶ let  $A$  be the set of all user that are the recipients of a message with a positive probability
- ▶  $A$  called the anonymity set of this message
- ▶ anonymity measure: the size of  $A$

Problem:

- ▶ if this size is low, then anonymity is poor
- ▶ if this size is high, it does not necessarily mean that anonymity is high, probabilities can differ substantially

## Highest probabilities

- ▶ anonymity measure: **the highest probability in the anonymity set**
- ▶ motivation: high probability means there is a quite probable location, even if many other locations are possible

## Entropy and anonymity set

- ▶ consider probabilities of locations in the anonymity set
- ▶ anonymity measure: **entropy of this probability distribution**
- ▶ motivation: entropy says how many bits in average are required to specify the location in the anonymity set

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

An obvious example: “pseudo-mix”

- ▶ input:  $n$  messages on positions 0 through  $n - 1$

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

An obvious example: “pseudo-mix”

- ▶ input:  $n$  messages on positions 0 through  $n - 1$
- ▶ cryptographic recoding of messages – as usual

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

An obvious example: “pseudo-mix”

- ▶ input:  $n$  messages on positions 0 through  $n - 1$
- ▶ cryptographic recoding of messages – as usual
- ▶ “permuting”:
  - ▶  $r < n$  chosen uniformly at random

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

An obvious example: “pseudo-mix”

- ▶ input:  $n$  messages on positions 0 through  $n - 1$
- ▶ cryptographic recoding of messages – as usual
- ▶ “permuting”:
  - ▶  $r < n$  chosen uniformly at random
  - ▶ a decoded message from position  $i$  moved to position  $i + r \bmod n$ .

## Problems with these definitions

- ▶ only one user considered
- ▶ dependencies among users may be crucial

An obvious example: “pseudo-mix”

- ▶ input:  $n$  messages on positions 0 through  $n - 1$
- ▶ cryptographic recoding of messages – as usual
- ▶ “permuting”:
  - ▶  $r < n$  chosen uniformly at random
  - ▶ a decoded message from position  $i$  moved to position  $i + r \bmod n$ .
- ▶ a message of adversary reveals  $r$  and thereby all anonymity is gone
- ▶ well, entropy for a single message is maximal

## Traffic analysis

consider a communication network, with (unbreakable)  
cryptographic recoding of the messages at the network nodes

## Traffic analysis

consider a communication network, with (unbreakable) cryptographic recoding of the messages at the network nodes

- ▶ how much gains an adversary by observing the traffic?

## Traffic analysis

consider a communication network, with (unbreakable) cryptographic recoding of the messages at the network nodes

- ▶ how much gains an adversary by observing the traffic?
- ▶ sometimes an adversary knows everything (the routes of messages do not cross, while the adversary see all links)

## Traffic analysis

consider a communication network, with (unbreakable) cryptographic recoding of the messages at the network nodes

- ▶ how much gains an adversary by observing the traffic?
- ▶ sometimes an adversary knows everything (the routes of messages do not cross, while the adversary see all links)
- ▶ destinations and sources often cannot be hidden, only linking them might be difficult

## Viewpoint without traffic information

- ▶ for each node the adversary knows:
  - ▶ how many messages are initially sent,
  - ▶ how many messages are finally delivered

## Viewpoint without traffic information

- ▶ for each node the adversary knows:
  - ▶ how many messages are initially sent,
  - ▶ how many messages are finally delivered
- ▶ random variable  $\pi$ :  
 $\pi(j) = i$  iff the  $i$ th message goes to the  $j$ th destination place
- ▶ probability distribution of  $\pi$  summarizes all information which an adversary can use

## View with traffic information

- ▶ the same as before, but additionally adversary knows which links have been used for communication

## View with traffic information

- ▶ the same as before, but additionally adversary knows which links have been used for communication
- ▶ sometimes it is evident that a certain message could not be delivered somewhere - no path exists

## Probability distribution

- ▶ now conditional probabilities:

$$\Pr[\pi|c]$$

where  $c$  is traffic information

- ▶ different  $c$  influence conditional probability in a different way,

## Probability distribution

- ▶ now conditional probabilities:

$$\Pr[\pi|c]$$

where  $c$  is traffic information

- ▶ different  $c$  influence conditional probability in a different way,
- ▶ goal of anonymity system: conditional probability distribution should be almost the same as the original one,
  - not always possible

## Probability distribution

- ▶ now conditional probabilities:

$$\Pr[\pi|c]$$

where  $c$  is traffic information

- ▶ different  $c$  influence conditional probability in a different way,
- ▶ goal of anonymity system: conditional probability distribution should be almost the same as the original one,  
– not always possible
- ▶ modified goal: get this property for almost all  $c$ , i.e. whp

## Distance of probability distributions

### Variation distance

- ▶ two probability distributions  $\mu_1$  and  $\mu_2$  over a finite space  $\Omega$
- ▶ definition of variation distance:

$$\|\mu_1 - \mu_2\| = \frac{1}{2} \sum_{\omega \in \Omega} |\mu_1(\omega) - \mu_2(\omega)| .$$

## Anonymity definition based on variation distance

$$\|\Pi - \Pi|C\| \leq \dots$$

where  $\Pi$  is probability distribution of  $\pi$ ,  
 $\Pi|C$  is probability distribution of  $\pi$  conditioned upon traffic information

## Anonymity definition based on mutual information

- ▶ information theoretic approach
- ▶ roughly speaking: how many information bits on  $\Pi$  is given by  $C$

## Anonymity definition based on mutual information

- ▶ information theoretic approach
- ▶ roughly speaking: how many information bits on  $\Pi$  is given by  $C$
- ▶ roughly equivalent to the previous definition – conversions possible (Berman, Fiat, Ta-Shma)

## Results on the onion protocol

Adversary with full knowledge on the traffic

## Results on the onion protocol

Adversary with full knowledge on the traffic

- ▶ Rackoff, Simon (ACM STOC'93):  
polylogarithmic time (degree 11),  
special assumption: at stage  $i$  the messages stay inside  
groups of cardinality  $2^i$

## Results on the onion protocol

Adversary with full knowledge on the traffic

- ▶ Rackoff, Simon (ACM STOC'93):  
polylogarithmic time (degree 11),  
special assumption: at stage  $i$  the messages stay inside  
groups of cardinality  $2^i$
- ▶ Czumaj, Kanarek, Kutyłowski, Loryś (ACM SODA'99):  
under the same assumptions - time  $O(\log^2 n)$

## Results on the onion protocol

Adversary with partial knowledge on the traffic

## Results on the onion protocol

Adversary with partial knowledge on the traffic

- ▶ Berman, Fiat, Ta-Shma (FC'2004) – adversary model,  $O(\log^4 n)$  steps for  $n$  messages and variation distance  $1/n$

## Results on the onion protocol

Adversary with partial knowledge on the traffic

- ▶ Berman, Fiat, Ta-Shma (FC'2004) – adversary model,  $O(\log^4 n)$  steps for  $n$  messages and variation distance  $1/n$
- ▶ Gomułkiewicz, Klonowski, Kutyłowski (ISC'2004) –  $O(\log n)$  steps, optimal result

## Rapid mixing and anonymity

consider a stochastic process of transmitting messages at random

- ▶ at every step the messages are recoded at the nodes and
- ▶ sent further to a random destination (chosen independently)

## Rapid mixing and anonymity

consider a stochastic process of transmitting messages at random

- ▶ at every step the messages are recoded at the nodes and
- ▶ sent further to a random destination (chosen independently)
- ▶ the adversary can see where the messages are sent (conditional probabilities are considered)

## Rapid mixing and anonymity

consider a stochastic process of transmitting messages at random

- ▶ at every step the messages are recoded at the nodes and
- ▶ sent further to a random destination (chosen independently)
- ▶ the adversary can see where the messages are sent (conditional probabilities are considered)

How many steps are needed until probability distribution becomes close to the uniform distribution?

## Stationary distribution

- ▶ a probability distribution over the set of states is **stationary** if applying a single step of the process does not change the probability distribution,

## Stationary distribution

- ▶ a probability distribution over the set of states is **stationary** if applying a single step of the process does not change the probability distribution,
- ▶ example: initially: a uniform distribution over permutations of  $k$  elements,  
apply a permutation chosen according to some distribution  $S$   
result: again a uniform distribution over the set of permutations of  $k$  elements.

## Rapid mixing techniques

- ▶ given a stochastic process  $\mathcal{P}$  with a uniform distribution  $u$
- ▶ show that after  $t$  steps the probability distribution of the process started in an arbitrary state is close to  $u$

## Rapid mixing techniques

- ▶ given a stochastic process  $\mathcal{P}$  with a uniform distribution  $u$
- ▶ show that after  $t$  steps the probability distribution of the process started in an arbitrary state is close to  $u$

How to construct such a proof?

## Coupling techniques

- ▶ define two processes  $\mathcal{P}_A, \mathcal{P}_B$
- ▶ both are the copies of  $\mathcal{P}$ ,

## Coupling techniques

- ▶ define two processes  $\mathcal{P}_A, \mathcal{P}_B$
- ▶ both are the copies of  $\mathcal{P}$ ,
- ▶ but the choices of the first process may influence the second process

## Coupling goal

- ▶ define dependencies so that the processes “converge”
  - (with probabilities growing with the number of steps) they reach the same state

## Coupling goal

- ▶ define dependencies so that the processes “converge”
  - (with probabilities growing with the number of steps) they reach the same state
- ▶ key property – coupling lemma:

$$\begin{aligned} & \text{variation distance after } t \text{ steps} \\ & \leq \\ & \Pr[\mathcal{P}_A \text{ and } \mathcal{P}_B \text{ differ after } t \text{ steps}]. \end{aligned}$$

## Why coupling lemma holds?

- ▶ let  $\mathcal{P}_B$  be started according to stationary distribution

## Why coupling lemma holds?

- ▶ let  $\mathcal{P}_B$  be started according to stationary distribution
- ▶ by definition of stationary distribution  $\mathcal{P}_B$  will stay in this distribution after each step

## Why coupling lemma holds?

- ▶ let  $\mathcal{P}_B$  be started according to stationary distribution
- ▶ by definition of stationary distribution  $\mathcal{P}_B$  will stay in this distribution after each step

what about  $\mathcal{P}_A$ ?

- ▶ start  $\mathcal{P}_A$  in an arbitrary state
- ▶ .. and use dependencies defined by coupling

## Why coupling lemma holds?

- ▶ key point: if probability that two processes differ is at most  $p$  then probability distributions cannot differ by more than  $p$ .

## Let's use coupling

- ▶ a universal tool for showing convergence
- ▶ no expertise in stochastic processes necessary - only combinatorial skills

## Path coupling

- ▶ it suffices to consider processes that are almost in the same state
  - ▶ distances between process states should be defined
  - ▶ it suffices to consider pair of processes at distance 1

## Example - anonymity for Chaum's scheme of electronic elections

- ▶ **proving security** of voters (well, with high probability)
- ▶ Gomułkiewicz, Klonowski, and myself, ESORICS'2003

## Chaums's scheme

- ▶ visual cryptography for convincing voters
- ▶ essential point: decoding of votes
- ▶ several decoding authorities:
  - ▶ Authority 1 decodes all votes, permutes at random, the results given to Authority 2
  - ▶ Authority 2 decodes all votes, permutes at random, the results given to Authority 3
  - ▶ ...

## Checking Authorities

- ▶ Authorities have to prove honesty of decoding and permuting
- ▶ selective proof (Randomized Partial Checking):  
for 50% randomly chosen positions permutation values must be revealed
- ▶ privacy concerns: may be it guarantees honesty of Authorities but at the price of voter's anonymity?

# Checking Authorities

## Modelling Randomized Partial Checking

after simple reformulation we get a process in which during a step

- ▶ elements on positions 1 through  $n/2$  are permuted at random,
- ▶ elements on positions  $n/2 + 1$  through  $n$  are permuted at random,
- ▶ a single permutation is applied to all elements even if this permutation is random, it is fixed when process is defined

## Coupling proof

- ▶ after the first step we have “white” and “black” elements,
- ▶ path coupling: consider the states which differ by just one transposition  $\tau$

## Definition of coupling

- ▶ if differences inside the same half, then define dependence:
  - ▶ if the first process chooses permutation  $\rho$  in this half,
  - ▶ then the second process chooses  $\rho \circ \tau$
- ▶ with such a dependence the difference disappears

## Definition of coupling - difficult case

- ▶ the first process has an extra black element in the first half, the second process has an extra black element in the second half
- ▶ it does not work as before

How to couple? In two steps!

## Constructing a coupling

- ▶ from the first half of white elements will go to the second half, while the rest will remain,
- ▶ similarly for the second half

## Constructing a coupling

- ▶ from the first half of white elements will go to the second half, while the rest will remain,
- ▶ similarly for the second half
- ▶ solution idea: exchange the location of the extra black item of the second process with the places of white elements

## Constructing a coupling

- ▶ constructing dependencies:
  - ▶ if the extra black element of the first process will go to **another** half  
then the extra black element of the second process takes a place to **remain** in its half

## Constructing a coupling

- ▶ constructing dependencies:
  - ▶ if the extra black element of the first process will go to **another** half  
then the extra black element of the second process takes a place to **remain** in its half
  - ▶ if the extra black element of the first process will **remain** in its half  
then the extra black element of the second process takes a place to go to **another** half

## Constructing a coupling

- ▶ constructing dependencies:
  - ▶ if the extra black element of the first process will go to **another** half  
then the extra black element of the second process takes a place to **remain** in its half
  - ▶ if the extra black element of the first process will **remain** in its half  
then the extra black element of the second process takes a place to go to **another** half
- ▶ minor technical difficulties: white elements do not split evenly between those that stay in the same half and those that go

Thanks for your attention!
